13. ABSTRACT (Maximum 200 words)  A mass spectrometer samples a neutral gas consisting of more than one component. During sampling, the component species are not only ionized, but also fragmented, thus introducing mass fragments not present in the original gas. A method has been developed that uses the resultant measured spectral intensity ratios to find the density or partial pressure ratios of the original components. In addition to spectral intensity ratios, the following is assumed to be known: the fragments produced from each original component; the branching ratios of these fragments; and the ratios of ionization efficiencies for each component pair. Since this method depends only on spectral and ionization ratios, it is in principle (although in practice, not completely) independent of the variable, and often time dependent, characteristics of individual instruments.

# Inversion for Mass Spectrometer Multicomponent Sampling

## 1. INTRODUCTION

This report addresses the problem of a mass spectrometer sampling a neutral gas consisting of more than one component. During sampling, the component species are not only ionized, but also fragmented, thus introducing mass fragments not present in the original gas. We want to use the resultant spectral intensity ratios to find the density or partial pressure ratios of the original components. In addition to the spectral intensity ratios, the following are assumed to be known: the fragments produced from each original component; the branching ratios of each of these fragments; and the ratios of ionization efficiencies for each component. In principle, all the known quantities are independent of particular mass spectrometer characteristics, such as multiplier gain for example, so that the procedure need not take into account the peculiarities of a specific instrument. It is required, however that the branching ratios and hence the electron beam energies be the same for both branching ratio and sample measurements.

Note the frequent reference to *ratios* of values rather than values per se. This is because many of these values vary from instrument to instrument, and further, for any given instrument, with time. As noted, we are seeking an inversion that is independent of instrument properties, such as ion source characteristics or multiplier gain. If these properties

are assumed to remain fixed, then inversion is quite simple. If they are not fixed, then the method described here, a more complicated procedure, or possibly some other procedure must be resorted to.

## 2. GENERAL SOLUTION OF THE PROBLEM

Let  $C_j$  be the density or partial pressure of the neutral compounds,  $m$  in number,  $j=1$  to  $m$ .

Let  $\alpha_j$  be the ionization efficiency of the  $j$ th component.

Let the  $B_{ij}$  be the spectral intensities of the  $i$ th fragment of the  $j$ th compound. This will be an array of  $n$  rows ( $i$  runs from 1 to  $n$ ) and  $m$  columns ( $j$  runs from 1 to  $m$ ). The rows identify fragments of a given mass (including in particular, the mass of the unfragmented ion); the columns identify a given input component.

Let  $I=I(j)$  index the mass of the  $j$ th unfragmented component, so that  $B_{Ij}$  when  $I$  is written without an argument is a one dimensional array, dependent on  $j$  only.  $B_{I(\ell)j}$ , however ( $I(\ell)$  written *with* an argument) is once again a member of a two dimensional array, with subscripts  $I(\ell)$  and  $j$ .

At this point, to clarify the notation, we illustrate by displaying a specific example. For this purpose we choose a gas having four components: CO, CO<sub>2</sub>, C<sub>2</sub>H<sub>4</sub>O<sub>2</sub>, and O<sub>2</sub>, and assume that the first two and last of these, but not the third, is decomposed into every possible fragment. Let the compounds be sequenced in the order given above. Then, the array for the  $B_{ij}$  looks as follows. ( $M$  is the fragment mass number).

Table 1. Illustrative Table of Symbolic Values for  $B_{ij}$ .

$\begin{array}{c} C_j \\ \hline M \end{array}$	$C_1$ (CO)	$C_2$ (CO <sub>2</sub> )	$C_3$ (C <sub>2</sub> H <sub>4</sub> O <sub>2</sub> )	$C_4$ (O <sub>2</sub> )
12	$B_{11}$	$B_{12}$	$B_{13}$	$B_{14} = 0$
16	$B_{21}$	$B_{22}$	$B_{23}$	$B_{24}$
28	$B_{31}$	$B_{32}$	$B_{33}$	$B_{34} = 0$
32	$B_{41} = 0$	$B_{42}$	$B_{43}$	$B_{44}$
44	$B_{51} = 0$	$B_{52}$	$B_{53}$	$B_{54} = 0$
60	$B_{61} = 0$	$B_{62} = 0$	$B_{63}$	$B_{64} = 0$

In general, most of the  $B_{ij}$  will be zero, but for this relatively small system they are not. We have,  $m = 4$ ,  $n = 6$ , and  $I(1) = 3$ :  $I(2) = 5$ :  $I(3) = 6$ :  $I(4) = 4$ .

This example will be used again in Section 3 to demonstrate a sample solution.

Returning now to the general development, we have the component conservation relations

$$\alpha_1 C_1 = \sum_{i=1}^n B_{i1} \quad (1a)$$

$$\alpha_2 C_2 = \sum_{i=1}^n B_{i2} \quad (1b)$$

$$\vdots$$

$$\alpha_j C_j = \sum_{i=1}^n B_{ij} \quad (1c)$$

$$\vdots$$

$$\alpha_m C_m = \sum_{i=1}^n B_{im} \quad (1d)$$

Let  $\rho_{ij} = \frac{B_{ij}}{B_{ij}}$  and  $\beta_j = \frac{\alpha_{j+1}}{\alpha_j}$ . The  $\rho_{ij}$  are relative branching ratios, and the  $\beta_j$  the ionization efficiency ratios referred to in the introduction.

$$\text{Let } y_j = \frac{C_j}{C_{j+1}}$$

Then

$$y_1 = \beta_1 \sum_{i=1}^n B_{i1} / \sum_{i=1}^n B_{i2} = \beta_1 \frac{B_{11}}{B_{12}} \sum_{i=1}^n \rho_{i1} / \sum_{i=1}^n \rho_{i2} \quad (2a)$$

$$y_2 = \beta_2 \sum_{i=1}^n B_{i2} / \sum_{i=1}^n B_{i3} = \beta_2 \frac{B_{12}}{B_{13}} \sum_{i=1}^n \rho_{i2} / \sum_{i=1}^n \rho_{i3} \quad (2b)$$

⋮

$$y_j = \beta_j \sum_{i=1}^n B_{ij} / \sum_{i=1}^n B_{i,j+1} = \beta_j \frac{B_{1j}}{B_{1,j+1}} \sum_{i=1}^n \rho_{ij} / \sum_{i=1}^n \rho_{i,j+1} \quad (2c)$$

⋮

$$y_{m-1} = \beta_{m-1} \sum_{i=1}^n B_{i,m-1} / \sum_{i=1}^n B_{im} = \beta_{m-1} \frac{B_{1,m-1}}{B_{1m}} \sum_{i=1}^n \rho_{i,m-1} / \sum_{i=1}^n \rho_{im} \quad (2d)$$

Let  $B_{ij}/B_{i,j+1} = x_j \quad : \quad j = 1 \text{ to } m-1 \quad : \quad x_m = 1$

and  $\sum_{i=1}^n \rho_{ij} / \sum_{i=1}^n \rho_{i,j+1} = S_j$ .

Then  $y_1 = \beta_1 x_1 S_1$

$$y_2 = \beta_2 x_2 S_2$$

⋮

$$y_k = \beta_k x_k S_k$$

⋮

$$y_{m-1} = \beta_{m-1} x_{m-1} S_{m-1}$$

(3)

The reason for the condensation of notation is that all  $\beta_k$  and  $S_k$  are known. We now need to obtain the  $x_k$  to complete the solution.

$$\text{Let } \Omega_1 = \sum_{j=1}^m B_{I(1)j} / \sum_{j=1}^m B_{I(2)j}$$

$$\Omega_2 = \sum_{j=1}^m B_{I(2)j} / \sum_{j=1}^m B_{I(3)j}$$

...

$$\Omega_k = \sum_{j=1}^m B_{I(k)j} / \sum_{j=1}^m B_{I(k+1)j}$$

...

$$\Omega_{m-1} = \sum_{j=1}^m B_{I(m-1)j} / \sum_{j=1}^m B_{I(m)j}$$

The  $\Omega_k$  are the intensity ratios of the MEASURED SPECTRAL LINES, having the masses of the unfragmented input compounds. We now show that the right hand sides of the expressions for  $\Omega_k$  can be expressed in terms of the  $\rho_{ij}$  and  $x_k$ . Since the  $\Omega_k$  are  $m-1$  in number these then constitute a closed set of simultaneous implicit equations for  $x_k$ . When solved for the  $x_k$  they give us the solutions for the required values of  $y_k$ .

We could just as easily have selected any other of the  $(m-1)!$  sets of spectral ratios formable from the intensities of the  $m$  unfragmented species. However, the choice made is readily identifiable and seems a natural choice. The manipulation of the expressions for  $\Omega_k$  to put them in terms of  $\rho_{ij}$  and  $x_k$  will be done for  $k = 1$ . The other relations then follow by augmentation of the  $k$  index.

$$\Omega_1 = \frac{B_{I(1)1} + B_{I(1)2} + \dots + B_{I(1)j} + \dots + B_{I(1)m}}{B_{I(2)1} + B_{I(2)2} + \dots + B_{I(2)j} + \dots + B_{I(2)m}} \quad (4a)$$

$$= \frac{B_{11} + B_{12} \rho_{I(1)2} + \dots + B_{1j} \rho_{I(1)j} + \dots + B_{1m} \rho_{I(1)m}}{B_{11} \rho_{I(2)1} + B_{12} + \dots + B_{1j} \rho_{I(2)j} + \dots + B_{1m} \rho_{I(2)m}} \quad (4b)$$

Note in the subscripts of B, the switch from argued I (I(1), I(2)) in Eq. (4a) to UNARGUMENTED I in Eq. (4b). This is preparatory to expressing ratios of  $B_{Ij}$  in terms of  $x_j$ . Next, divide numerator and denominator by  $B_{Im}$  and observe that

$$B_{Ij}/B_{Im} = x_j x_{j+1} \cdots x_{m-1} = \prod_{i=j}^{m-1} x_i \quad (5)$$

so that

$$\Omega_1 = \sum_{j=1}^m \rho_{I(1)j} \prod_{i=j}^m x_i / \sum_{j=1}^m \rho_{I(2)j} \prod_{i=j}^m x_i. \quad (6a)$$

(In these as well as the remaining sums, we have

$$\rho_{I(1)1} = \rho_{I(2)2} = \cdots \rho_{I(j)j} = \cdots \rho_{I(m-1),m-1} = 1).$$

In like manner,

$$\Omega_2 = \sum_{j=1}^m \rho_{I(2)j} \prod_{i=j}^m x_i / \sum_{j=1}^m \rho_{I(3)j} \prod_{i=j}^m x_i \quad (6b)$$

⋮

$$\Omega_k = \sum_{j=1}^m \rho_{I(k)j} \prod_{i=j}^m x_i / \sum_{j=1}^m \rho_{I(k+1)j} \prod_{i=j}^m x_i \quad (6c)$$

⋮

$$\Omega_{m-1} = \sum_{j=1}^m \rho_{I(m-1)j} \prod_{i=j}^m x_i / \sum_{j=1}^m \rho_{I(m)j} \prod_{i=j}^m x_i \quad (6d)$$

Let  $z_j = \prod_{i=j}^m x_i$ ;  $1 \leq j \leq m$ .

Then, clearing the kth equation of fractions

$$\Omega_k \sum_{j=1}^m \rho_{I(k+1)j} z_j = \sum_{j=1}^m \rho_{I(k)j} z_j. \quad (7)$$

Let  $A_{jk} = \Omega_k \rho_{I(k+1)j} - \rho_{I(k)j}$ .

Then

$$\sum_{j=1}^m A_{jk} z_j = 0 \quad 1 \leq k \leq m-1 \quad (8)$$

form a set of  $m-1$  linear equations for the  $m-1$  unknowns  $z_j$  which can be solved by one of the usual methods. Following this, the  $x_j$  are recovered from

$$x_j = z_j / z_{j+1} \quad 1 \leq j \leq m-1.$$

This completes the solution.

### 3. EXAMPLE

To illustrate these ideas, we first assign values to the array for the  $B_{ij}$  shown in Table 1 and also to the required values of  $\alpha_j$  the ionization efficiencies. Here, the units for the values of  $B_{ij}$  (the spectral intensities of the  $i$ th mass fragment from the  $j$ th compound) may be taken as microamperes; and those for the ionization efficiencies, when normalized to a pressure of one Torr, as microamperes per Torr. Note that the column sum of spectral intensities is set equal to the corresponding value of  $\alpha_j$ . This assignment is somewhat arbitrary. Strictly, the sum of the branching ratios for each component is unity, and dividing each value of  $B_{ij}$  by  $\alpha_j$  will yield this result. If the  $B_{ij}$  are the actual fragment spectral intensities due to an arbitrary mixture of gases, neither of these is true; each column will be multiplied by an (unknown) constant, dependent on the partial pressure of that particular component. Only with this assignment will Eq. (1) be true. These constant values however, are precisely those we are seeking with

this treatment, and so are not known. However, since all equations except Eq. (1) deal only with RELATIVE values for all variables, the actual values as well as the units turn out to be of no import. Only the RELATIVE VALUES in each column are required. To the right of the array, are listed the intensities of the MEASURED mass spectrum. From these, will be formed the three (= m-1) values of  $\Omega_k$  required for solution. We note that none of the values given here are actual measured values; those for CO, CO<sub>2</sub> and O<sub>2</sub> are reasonable, but all have been fabricated for purposes of illustrating the method of solution.

Table 2. Values of  $B_{ij}$ .

$M \backslash C_j$	$C_1$ (CO)	$C_2$ (CO <sub>2</sub> )	$C_3$ (C <sub>2</sub> H <sub>4</sub> O <sub>2</sub> )	$C_4$ (O <sub>2</sub> )	Measured Spectral Intensities
12	0.0025	0.0009	0.005	0	0.002
16	0.05	0.03	0.01	0.15	0.2
28	0.5	0.06	0.02	0	0.4
32	0	0.0009	0.005	1.5	1
44	0	0.3	0.02	0	1
60	0	0	0.2	0	2
$\alpha_1$	0.5525	0.3919	0.260	1.65	

Next we form the table of the  $\rho_{ij}$  by dividing  $B_{ij}/B_{ij}$ . We also form the  $\Omega_j$ , and the  $\beta_j$ .

Table 3. Values of  $\rho_{ij}$ ,  $\Omega_j$ , and  $\beta_j$ .

$M \backslash C$	$C_1$ (CO)	$C_2$ (CO <sub>2</sub> )	$C_3$ (C <sub>2</sub> H <sub>4</sub> O <sub>2</sub> )	$C_4$ (O <sub>2</sub> )	$\Omega$
12	0.005	0.003	0.025	0	$\Omega_1 = 0.4/1 = 0.4$
16	0.1	0.1	0.05	0.1	
28	1.0	0.2	0.1	0	$\Omega_2 = 1/2 = 0.5$
32	0	0.003	0.025	1.0	
44	0	1.0	0.1	0	$\Omega_3 = 2/1 = 2.0$
60	0	0	1.0	0	
$\beta_1 = 0.709 \quad \beta_2 = 0.663 \quad \beta_3 = 6.35$					

From these,

$$S_1 = \frac{1.105}{1.360} = 0.8271; \quad S_2 = \frac{1.360}{1.300} = 1.046; \quad S_3 = \frac{1.300}{1.100} = 1.182$$

and

$$y_1 = 0.5864 x_1; \quad y_2 = 0.6935 x_2; \quad y_3 = 7.506 x_3.$$

To complete the solution, we next form the equations for the  $x_k$ .

$$\Omega_1 = \frac{x_1 x_2 x_3 + 0.2 x_2 x_3 + 0.1 x_3 + 0}{0 + x_2 x_3 + 0.1 x_3 + 0} = \frac{x_1 x_2 + 0.2 x_2 + 0.1}{x_2 + 0.1}$$

$$\Omega_2 = \frac{0 + x_2 x_3 + 0.1 x_3 + 0}{0 + 0 + x_3 + 0} = x_2 + 0.1$$

$$\Omega_3 = \frac{0 + 0 + x_3 + 0}{0 + 0.003 x_2 x_3 + 0.025 x_3 + 1} = \frac{x_3}{0.003 x_2 x_3 + 0.025 x_3 + 1}.$$

Here, the system is so simple we need not introduce the  $z_j$ ; instead we find directly

$$x_1 = 0.05; \quad x_2 = 0.40; \quad x_3 = 2.111$$

and

$$y_1 = [\text{CO}]/[\text{CO}_2] = 0.02932$$

$$y_2 = [\text{CO}_2]/[\text{C}_2\text{H}_4\text{O}_2] = 0.2774$$

$$y_3 = [\text{C}_2\text{H}_4\text{O}_2]/[\text{O}_2] = 15.84$$

#### 4. THE DEGENERATE CASE

It may turn out that two (or possibly more) of the unfragmented input compounds have identical masses. A good example of this would be the presence in the measured sample of  $\text{CO}_2$  and  $\text{N}_2\text{O}$ . Since this only appears as a single peak in the measured spectrum, we would then seem not to have the required  $m-1$  values of  $\Omega_k$  needed to complete the solution. If however, the sum of the components is treated as a single component, we can still obtain, instead of the  $m-1$ ,  $m-2$  ratios of the input components, with the sum of the degenerate components appearing as a single component.

#### 5. UNRESOLVED ISSUES

We have tacitly assumed that real, positive solutions for the  $x_k$  can always be found. This seems to be intuitively clear on the following grounds. If instead of inversion, we start from any known mixture, we will always produce a specific spectrum containing both unfragmented and fragmented spectral lines. Thus, when the process IS inverted, we know that a solution exists; it is reasonable to assume then, that this solution will be obtained. Still, such reasoning does not constitute a proof, and no proof has yet been found.

If this reasoning is correct however, we have here a means of checking on the quality of experimental data. If a solution cannot be found, then this indicates that there is an inconsistency between the spectra measured, the measured branch ratios, and the measured ionization efficiencies. One aspect of this question might be pursued further by investigating the way assumed errors in the measured spectra are propagated backward into the calculated original components.

Another question is whether it is possible by further work to find the ratio of input compounds even when they do have the same mass. This issue is not pursued further here.
